

II. MEXICO

SUMMARY

Mexico has excellent potential for developing its shale gas and oil resources stored in marine-deposited, source-rock shales distributed along the onshore Gulf of Mexico region.

Figure II-1. Onshore Shale Gas and Shale Oil Basins of Eastern Mexico's Gulf of Mexico Basins.

Source: ARI, 2013.

June, 2013

II-1

Technically recoverable shale resources, estimated at 545 Tcf of natural gas and 13.1 billion barrels of oil and condensate, are potentially larger than the country's proven conventional reserves, Table II-1. The best documented play is the Eagle Ford Shale of the Burgos Basin, where oil- and gas-prone windows extending south from Texas into northern Mexico have an estimated 343 Tcf and 6.3 billion barrels of risked, technically recoverable shale gas and shale oil resource potential, Table II-2.

Further to the south and east within Mexico, the shale geology of the onshore Gulf of Mexico Basin becomes structurally more complex and the shale development potential is less certain. The Sabinas Basin has an estimated 124 Tcf of risked, technically recoverable shale gas resources within the Eagle Ford and La Casita shales, but the basin is faulted and folded. The structurally more favorable Tampico, Tuxpan, and Veracruz basins add another 28 Tcf and 6.8 billion barrels of risked, technically recoverable shale gas and shale oil potential from Cretaceous and Jurassic marine shales. These shales are prolific source rocks for Mexico's conventional onshore and offshore fields in this area. Shale drilling has not yet occurred in these southern basins.

PEMEX envisions commercial shale gas production being initiated in 2015 and increasing to around 2 Bcfd by 2025, with the company potentially investing \$1 billion to drill 750 wells. However, PEMEX's initial shale exploration wells have been costly (\$20 to \$25 million per well) and have provided only modest initial gas flow rates (~3 million ft³/d per well with steep decline). Mexico's potential development of its shale gas and shale oil resources could be constrained by several factors, including potential limits on upstream investment, the nascent capabilities of the local shale service sector, and public security concerns in many shale areas.

INTRODUCTION

Mexico has large, geologically prospective shale gas and shale oil resources in the northeastern part of the country within the onshore portion of the greater Gulf of Mexico Basin, Figure II-1. These thick, organic-rich shales of marine origin correlate with productive Jurassic and Cretaceous shale deposits in the southern United States, notably the Eagle Ford and Haynesville shales, Figure II-2.¹ To date, Mexico's national oil company PEMEX has drilled at least six shale gas/oil exploration wells with modest results. The company plans to accelerate shale activity during the next few years, budgeting 6.8 billion pesos (575 million USD) in 2014.

Whereas Mexico's marine-deposited shales appear to have good rock quality, the geologic structure of its sedimentary basins often is considerably more complex than in the USA. Compared with the broad and gently dipping shale belts of Texas and Louisiana, Mexico's coastal shale zone is narrower, less continuous and structurally more disrupted. Regional compression and thrust faulting related to the formation of the Sierra Madre Ranges have squeezed Mexico's coastal plain, creating a series of discontinuous sub-basins.² Many of Mexico's largest conventional oil and gas fields also occur in this area, producing from conventional sandstone reservoirs of Miocene and Pliocene age that were sourced by deep, organic-rich and thermally mature Jurassic and Cretaceous-age shales. These deep source rocks are the principal targets for shale gas/oil exploration in Mexico.

Figure II-2. Cross-Section of Shale Targets in Eastern Mexico.

Source: Escalera Alcocer, 2012.

Improved geologic data coverage collected since ARI's initial 2011 estimate indicates that Mexico's prospective areas for shale gas -- particularly in the structurally more complex basins -- are slightly smaller than previously mapped. Furthermore, several of the previously mapped dry gas areas are now known to be within the wet gas to oil thermal maturity windows. On the other hand, geologic risk factors have been reduced due to the demonstration of the presence of productive hydrocarbons and improved geologic control. On an overall energy-equivalent basis, our updated estimate of Mexico's shale resources is about 10% lower than our earlier 2011 estimate (624 Tcfe in this study vs 681 Tcf previously).

PEMEX has identified some 200 shale gas resource opportunities in five geologic provinces in eastern Mexico, Figure II-3. According to the company, prospective regions include 1) Paleozoic shale gas in Chihuahua region; 2) Cretaceous shale gas in the Sabinas-Burro-Picachos region; 3) Cretaceous shale gas in the Burgos Basin; 4) Jurassic shale gas in Tampico-Misantla; and 5) unspecified shale gas potential in Veracruz.

Figure II-3. PEMEX Map Identifying Mexico's Shale Gas Potential (November 2012)

Source: PEMEX, 2012b.

PEMEX's initial internal evaluation estimated 150 Tcf (P90) to 459 Tcf (P10) of recoverable shale gas resources, with a median estimate of 297 Tcf. In 2012 PEMEX updated its shale gas and shale oil resource assessment to 141.5 Tcf of shale gas (comprising 104.7 Tcf dry and 36.8 Tcf wet) and 31.9 billion barrels of shale oil and condensate.

Initial shale gas and shale oil exploration began in Mexico in late 2011. PEMEX has drilled at least six wells in the Eagle Ford Shale play in northern Mexico to date, but the southern shale basins have not yet been tested. Despite some areas with favorable shale geology, Mexico faces significant obstacles to shale development. The country's upstream oil industry is largely closed to foreign investment. None of the shale-discovering independent E&P's, which unlocked the North American shale plays, are active in Mexico. And, well services for shale development are costlier than in the U.S. and Canada.

Onshore eastern Mexico contains a series of medium-sized basins and structural highs (platforms) within the larger western Gulf of Mexico Basin.³ These structural features contain organic-rich marine shales of Jurassic and Cretaceous age that appear to be the most prospective for shale gas and oil development. The arcuate coastal shale belt includes the Burgos, Sabinas, Tampico, Tuxpan Platform, and Veracruz basins and uplifts. Because detailed geologic maps of these areas generally are not readily available, ARI constructed the general pattern of shale depth and thickness from a wide range of published local-scale maps and structural cross-sections.

Many of Mexico's shale basins are too deep in their center for shale gas and shale oil development (>5 km), while their western portions tend to be overthrust and structurally complex. However, the less deformed eastern portions of these basins and adjacent shallower platforms are structurally more simple. Here, the most prospective areas for shale gas and shale oil development are buried at suitable depths of 1 km to 5 km over large areas.

Pyrolysis geochemistry, carbon isotope studies, and biomarker analysis of oil and gas fields identify three major Mesozoic hydrocarbon source rocks in Mexico's Gulf Coast Basin: the Upper Cretaceous (Turonian to Santorian), Lower-Mid Cretaceous (Albian-Cenomanian), and -- most importantly -- Upper Jurassic (Tithonian), the latter having sourced an estimated 80% of the conventional oil and gas discovered in this region.⁴ These targets, particularly the Tithonian, also appear to have the greatest potential for shale gas development, Figure II-4.

The following sections discuss the shale gas and shale oil geology of the individual sub-basins and platforms along eastern Mexico's onshore Gulf of Mexico Basin. The basins discussed start in northern Mexico near the Texas border moving to the south and southeastern regions close to the Yucatan Peninsula.

Figure II-4. Stratigraphy of Jurassic and Cretaceous rocks in the Gulf of Mexico Basin, Mexico and USA.
Shale gas targets are highlighted.

Modified from Salvador and Quezada-Muneton, 1989.

1. BURGOS BASIN (Eagle Ford and Tithonian Shales)

1.1 Geologic Setting

Located in northeastern Mexico's Coahuila state, directly south of the Rio Grande River, the Burgos Basin covers an onshore area of approximately 24,200 mi², excluding its extension onto the continental shelf of the Gulf of Mexico, Figure II-5. The Burgos Basin is the southern extension of the Maverick Basin in Texas, the latter hosting the productive Eagle Ford and Pearsall shale plays.

The Burgos Basin expanded during the Early Jurassic and developed into a restricted carbonate platform, with thick salt accumulations that later formed a regional structural detachment as well as isolated diapirs. Structural deformation took place during the late Cretaceous Laramide Orogeny, resulting in some degree of faulting and tilting within the Burgos Basin. However, this tectonic event was focused more on the Sabinas Basin and Sierra Madre Oriental, while the Burgos remains structurally relatively simple and favorable for shale development.⁵ Thick Tertiary-age clastic non-marine deposits overlie the Jurassic and Carbonate marine sequences, reflecting later alternating transgressions and regressions of sea level in northeastern Mexico.⁶

The two most prospective shale targets in Mexico are present in the Burgos Basin: the Cretaceous (mainly Turonian) Eagle Ford Shale play and the Jurassic (mainly Tithonian) La Casita and Pimienta formations, Figure II-6. The Eagle Ford Shale in Mexico is the direct extension of its commercially productive Texas equivalent, whereas the La Casita and Pimienta formations correlate with the productive Haynesville Shale of the East Texas Basin. The La Casita is believed to be the main source rock for conventional Tertiary clastic reservoirs (Oligocene Frio and Vicksburg) in the southeastern Burgos Basin, with oil transported via deep-seated normal faults.⁷

1.2 Reservoir Properties (Prospective Area)

Eagle Ford Shale. Based on analogy with the Eagle Ford Shale in Texas, industry and ARI considers the Eagle Ford Shale in the Burgos Basin to be Mexico's top-ranked shale prospect. The Eagle Ford Shale is continuous across the western margin of the Burgos Basin, where the overall formation interval ranges from 100 to 300 m thick (average 200 m).⁸ Recognizing the sparse regional depth and thickness control on the Eagle Ford Shale in the

Burgos Basin,⁹ we relied on a recent PEMEX shale map to estimate a prospective area of 17,300 mi², slightly less than our previous estimate of 18,100 mi², comprising three distinct areas where the shale lies within the 1 km to 5 km depth window, Figure II-5. The eastern onshore portion of the Burgos Basin is excluded as the shale is deeper than 5 km.

Figure II-5. Burgos Basin Outline and Shale Gas and Shale Oil Prospective Areas.

Source: ARI, 2013.

Figure II-6. Stratigraphic Cross-Section Along the Western Margin of the Burgos Basin.

Section is flattened on top Cretaceous.

The Eagle Ford Shale (EF) here ranges from about 100 to 300 m thick (average 200 m).

Modified from Horbury et al., 2003.

Net organically-rich shale thickness within the prospective area ranges from 200 to 300 ft. Total organic content (TOC) is estimated to average 5%. Vitrinite reflectance (R_o) ranges from 0.85% to 1.6% depending on depth. Over-pressured reservoir conditions are common in this basin and a pressure gradient of 0.65 psi/ft was assumed. The surface temperature in this region averages approximately 20°C, while the geothermal gradient typically is 23°C/km. Porosity is not known but assumed to be comparable to the Texas Eagle Ford Shale play at about 10%.

La Casita and Pimienta (Tithonian) Shales. Several thousand feet deeper than the Eagle Ford Shale, the La Casita and Pimienta shales (Upper Jurassic Tithonian) are considered the principal source rocks in the western Burgos Basin. Extrapolating from the structure of the younger Eagle Ford, the average depth of the Tithonian Shale is 11,500 ft, with a prospective range of 5,000 to 16,400 ft. Gross formation thicknesses can be up to 1,400 ft, with an organically rich net pay of about 200 ft. TOC of 2.6% to 4.0%, averaging 3.0%, consists mainly of Type II kerogen that appears to be entirely within the dry gas window (1.30% R_o) with little to no liquids potential.¹⁰ Reservoir pressure and temperature conditions are similar to those in the Eagle Ford Shale play.

1.3 Resource Assessment

Eagle Ford Shale. Within its 17,300-mi² prospective area, the Eagle Ford Shale exhibits a high resource concentration of up to 191 Bcf/mi². Risked shale gas in-place (OGIP) totals 1,222 Tcf with risked shale oil in-place (OOIP) of 106 billion barrels. Risked, technically recoverable resources are estimated to be 343 Tcf of shale gas and 6.3 billion barrels of shale oil and condensate.

Tithonian Shale. Within the high-graded prospective area of 6,700 mi², the Tithonian La Casita and Pimienta shales are estimated to have approximately 50 Tcf of risked, technically recoverable dry gas resources from 202 Tcf of risked gas in-place. Resource concentration is about 100 Bcf/mi².

1.4 Recent Activity

PEMEX initiated conventional exploration in the Burgos Basin in 1942, discovering some 227 mostly natural gas fields in this basin to date. Currently, there are about 3,500 active natural gas wells producing in the Burgos Basin. These conventional reservoirs typically have low permeability with rapidly declining gas production. Due to restrictions on upstream oil and gas investment in Mexico, PEMEX is the only company that has conducted shale exploration activity in the Burgos Basin to date.

PEMEX made its first shale discovery in the Burgos Basin during late 2010 and early 2011, drilling the Emergente-1 shale gas well located a few kilometers south at the Texas/Coahuila border on a continuation of the Eagle Ford Shale trend from Texas. This initial horizontal well was drilled to a vertical depth of about 2,500 m and employed a 2,550-m lateral (although another source reported 1,364-m). Following a 17-stage fracture stimulation, the \$20-25 million well tested at a modest initial rate of 2.8 million ft³/day (time interval not reported), which would not be economic at current gas prices.¹¹

As of its last report (November 2012), PEMEX had drilled four shale gas exploration wells in the Eagle Ford play of the Burgos Basin with one shale exploration well in the Sabinas basin, reporting initial production for three wells. These wells include the Nómada-1 well situated in the oil window, the Habano-1 well (IP 2.771 million ft³/day gas with 27 bbl/day crude) and the Montañés-1 well in the wet gas window of the Burgos Basin. The dry gas window in the Burgos Basin was tested by the Emergente-1. The Percutor-1 (IP 2.17 million ft³/day) tested the

dry gas window in the Sabinas Basin. PEMEX has announced also drilled and produced gas from the Arbolero-1 well (3.2 million ft³/day), the first test of the Jurassic shale in this basin.¹² PEMEX plans to drill up to 75 shale exploration wells in the Burgos Basin through 2015.

2. SABINAS BASIN (Eagle Ford and Tithonian Shales)

2.1 Geologic Setting

The Sabinas is one of Mexico's largest onshore marine shale basins, extending over a total area of 35,700 mi² in the northeast part of the country, Figure II-7. The basin initially expanded during Jurassic time with a northeast-southwest trending structural fabric and was later strongly affected by the Late Cretaceous Laramide Orogeny. Structurally complex, the Sabinas Basin has been deformed into a series of tight, NW-SE trending, evaporate-cored folds of Laramide origin called the Sabinas Foldbelt. Dissolution of Lower Jurassic salt during early Tertiary time introduced a further overprint of complex salt-withdrawal tectonics.¹³ Much of the Sabinas Basin is too structurally deformed for shale gas development, but a small area on the northeast side of the basin is more gently folded and may be prospective.

Petroleum source rocks in the Sabinas Basin include the Cretaceous Olmos (Maastrichtian) and Eagle Ford Shale (Turonian) formations and the Late Jurassic (Tithonian) La Casita Formation. The latter two units contain marine shales with good petrophysical characteristics for shale development.¹⁴ In contrast, the Olmos Formation is primarily a non-marine coaly unit that, while a good source rock for natural gas¹⁵ as well as a coalbed methane exploration target in its own right,¹⁶ appears to be too ductile for shale development.

2.2 Reservoir Properties (Prospective Area)

Eagle Ford Shale. The Eagle Ford Shale is distributed across the NW, NE, and central portions of the Sabinas Basin. The target is the 300-m thick sequence of black shales rhythmically interbedded with sandy limestone and carbonate-cemented sandstone. We estimated a 500-ft thick organic-rich interval with 400 feet of net pay. We considered the Eagle Ford Shale in the Maverick Basin of South Texas as the analog for reservoir properties, using a TOC of 4% and a thermal maturity of 1.50% (R_o). Our estimate of porosity was increased to 5% based on the rock fabric and correlation with the Texas Eagle Ford Shale analog. The average depth for the prospective Eagle Ford is approximately 9,000 feet. Based on reported data, mostly from coal mining areas, we use a slightly under-pressured gradient of 0.35 psi/ft for the Sabinas Basin.

Figure II-7. Sabinas Basin Outline and Shale Gas Prospective Area.

Source: ARI, 2013.

La Casita Formation. This Tithonian-age unit, regarded as the primary hydrocarbon source rock in the Sabinas Basin, consists of organic-rich shales deposited in a deepwater marine environment. The La Popa sub-basin is one of numerous sub-basins within the Sabinas Basin, Figure II-8.^{17,18} The La Popa is a rifted pull-apart basin that contains thick source rock shales. Up to 370 m of black carbonaceous limestone is present overlying several km of evaporitic gypsum and halite. Total shale thickness in the La Casita ranges from 60 m to 800 m. Thick (300 m) and prospective La Casita Fm shales have been mapped at depths of 2,000 to 3,000 m in the central Sabinas Basin. Nearby, a thicker sequence (400-700 m) was mapped at greater depth (3,000 to 4,000 m).

The high-graded prospective area for the La Casita Formation averages 11,500 ft deep, about 2,500 ft deeper than the Eagle Ford Shale. The La Casita Formation averages about 240 ft of net pay thickness within an 800-ft thick organic-rich interval and has 2.0% average TOC that is gas prone (2.5% R_o). Our estimate of porosity in the La Casita was increased to 5% based on the rock fabric and correlation with the deep Texas and Louisiana Haynesville Shale analog.

2.3 Resource Assessment

Eagle Ford Shale. The Eagle Ford Shale unit is the larger shale gas target in the Sabinas Basin, with an estimated 100 Tcf of technically recoverable shale gas resource out of 501 Tcf of risked shale gas in-place within the 9,500-mi² prospective area. The average resource concentration is high at 132 Bcf/mi².

La Casita Formation. The secondary target in the Sabinas Basin, the underlying La Casita Formation, has an estimated 24 Tcf of technically recoverable shale gas out of 118 Tcf of risked shale gas in-place. Its resource concentration is estimated at 69 Bcf/mi².

2.4 Recent Activity

PEMEX has drilled one shale gas exploration well in the Sabinas Basin, confirming the continuation of the Eagle Ford Shale play. The Percutor-1 horizontal well, completed in March 2012, produced dry gas from a sub-surface depth of 3,330-3,390 m. The well's initial production rate was a modest 2.17 million ft³/day (measurement time interval not specified), with production reportedly declining rapidly.

Figure II-8. Geologic Map of the La Popa Sub-Basin, Southeastern Portion of the Sabinas Basin.

Note the numerous detachment and salt-controlled folds.

Source: Hudson and Hanson, 2010.

3. TAMPICO BASIN (Pimienta Shale)

3.1 Geologic Setting

Bounded on the west by the fold-and-thrust belt of the Sierra Madre Oriental (Laramide) and on the east by the Tuxpan platform, the Tampico-Mizatlan Basin extends north from the Santa Ana uplift to the Tamaulipas arch north of Tampico, Figure II-9. At the northern margin of the basin is an arch, limited by a series of faults extending south from the Tamaulipas arch.

Figure II-9. Prospective Pimienta Formation (Tithonian) Shale, Tampico Basin.

Source: ARI, 2013.

The principal source rock in the Tampico Basin is the Upper Jurassic (Tithonian) Pimienta Shale, Figure II-10. Although quite deep over much of the basin, the Pimienta reaches shale-prospective depths of 1,400 to 3,000 m in the south where three uplifted structures occur. The 40-km long, NE-SW trending Piedra de Cal anticline in the southwest Bejuco area has Pimienta Shale cresting at 1,600-m depth. The 20-km long, SW-NE trending Jabonera syncline in southeast Bejuco has maximum shale depth of 3,000 m in the east and minimum depth of about 2,400 m in the west. A system of faults defines the Bejuco field in the center of the area. Two large areas (Llano de Bustos and La Aguada) lack upper Tithonian shale deposits.

Figure II-10. Structural Cross-Section of the Tampico Basin

Source: Escalera Alcocer, 2012.

3.2 Reservoir Properties

Near the city of Tampico, some 50 conventional wells have penetrated organic-rich shales of the Pimienta Formation at depths of about 1,000 to 3,000 m. Three distinct thermal maturity windows (dry gas, wet gas, and oil) occur from west to east, reflecting the gentle structural dip angle in this basin. Average shale depth ranges from 5,500 to 8,000 ft. Excluding the paleo highs, the prospective area of the Pimienta Shale totals approximately 13,600 mi². Detailed shale thickness data are not available, but the Pimienta Fm here generally ranges from 200 m thick to as little as 10 m thick on paleo highs. We estimate an average net shale thickness of about 200 ft, out of the total organically rich interval of 500 ft within the prospective area. Average net shale TOC is estimated at 3%, with average thermal maturity ranging from 0.85% to 1.4% R_o .

3.3 Resource Assessment

The Pimienta Shale in the Tampico Basin holds an estimated 23 Tcf and 5.5 billion barrels of risked, technically recoverable shale gas and shale oil resources, out of risked OOIP and OGIP of 151 Tcf and 138 billion barrels, respectively. The shale gas resource concentration averages 19 to 83 Bcf/mi² while the shale oil concentration averages 17 to 38 million bbl/mi².

3.4 Recent Activity

PEMEX reported that it is evaluating the shale geology of the Tampico Basin and plans to drill up to 80 shale exploration wells through 2015.¹⁹

4. TUXPAN PLATFORM (Pimienta and Tamaulipas Shales)

4.1 Geologic Setting

The Tuxpan Platform, located southeast of the Tampico Basin, is a subtle basement high that is capped with a well-developed Early Cretaceous carbonate platform.²⁰ A particularly prospective and relatively well defined shale gas deposit is located in the southern Tuxpan Platform. Approximately 50 km south of the city of Tuxpan, near Poza Rica, a dozen or so conventional petroleum development wells in the La Mesa Syncline area penetrated thick organic-rich shales of the Pimienta (Tithonian) and Tamaulipas (Lower Cretaceous) Formations.²¹

A detailed cross-section of the Tuxpan Platform shows thick Lower Cretaceous and Upper Jurassic source rocks dipping into the Gulf of Mexico Basin, Figure II-11. These source rocks reach prospective depths of 2,500 m. Thermal maturity ranges from oil- to gas-prone.

4.2 Reservoir Properties (Prospective Area)

Pimienta Fm. The organically rich portion of the Jurassic Pimienta Shale averages about 500 ft thick in the high-graded area, with net thickness estimated at 200 ft. However, southeast of Poza Rica some areas the shale is thin or absent, probably due to submarine erosion or lack of deposition, Figure 12. The gamma ray log response in the organic-rich Pimienta Shale indicates moderate TOC of 3.0%, which is in the oil to wet gas window (average R_o of 0.9%). Depth ranges from 6,600 to 10,000 ft, averaging about 8,500 ft.

Tamaulipas Fm. The Lower Cretaceous Tamaulipas Fm spans a depth range of 6,000 to 9,500, averaging about 7,900 ft. The organic-rich interval averages 300 ft thick, with net pay estimated at about 210 ft. TOC is estimated to be 3.0%. The average thermal maturity is slightly lower than for the deeper Pimienta, at 0.85% R_o .

Source: ARI, 2013.

4.3 Resource Assessment

Pimienta Fm. In the Tuxpan Platform, the prospective area of the Pimienta Fm shale is estimated to be approximately 1,000 mi². Risked, technically recoverable resources are estimated to be about 1 Tcf of shale gas and 0.5 billion barrels of shale oil and condensate. Risked shale resource in-place is estimated at 10 Tcf and 12 billion barrels.

Tamaulipas Fm. Due to limited data on the younger Tamaulipas Fm the same prospective area of the Pimienta Shale was assumed (1,000 mi²). The Tamaulipas Shale is estimated to have risked technically recoverable resources of about 1 Tcf of shale gas and 0.5 billion barrels of shale oil and condensate, out of risked shale resources in-place of 9 Tcf and 13 billion barrels.

4.4 Recent Activity

No shale gas or oil exploration activity has been reported on the Tuxpan Platform.

5. VERACRUZ BASIN (Maltrata Shale)

5.1 Geologic Setting

The Veracruz Basin extends over an onshore area of 9,030 mi², near its namesake city. The basin's western margin is defined by thrustured Mesozoic carbonates (early Tertiary Laramide Orogeny) of the Cordoba Platform and Sierra Madre Oriental, Figure II-13. The basin is asymmetric in cross section, with gravity showing the deepest part along the western margin, Figure II-14.²² The basin comprises several major structural elements, from west to east: the Buried Tectonic Front, Homoclinal Trend, Loma Bonita Anticline, Tlacotalpan Syncline, Anton Lizardo Trend, and the highly deformed Coatzacoalcos Reentrant in the south.²³

A recent shale exploration map released by PEMEX indicates the prospective area of the Veracruz Basin is much smaller than previously assumed in the 2011 EIA/ARI study. This is because the shale is shown to be dipping at a steeper angle than previously mapped. In addition, both shale gas and oil thermal maturity windows are present.

5.2 Reservoir Properties (Prospective Area)

Maltrata Fm. The Upper Cretaceous (Turonian) Maltrata Formation is a significant source rock in the Veracruz Basin, containing an estimated 300 ft of organic-rich, shaly marine limestone. TOC ranges from 0.5% to 8%, averaging approximately 3%, and consists of Type II kerogen. Thermal maturity ranges from oil-prone (R_o averaging 0.85%) within the oil window at depths of less than 11,000 ft, to gas-prone (R_o averaging 1.4%) within the gas window at average depths below 11,500 ft.

5.3 Resource Assessment

Maltrata Fm. Whereas we previously had assumed that 90% of the Veracruz Basin (8,150 mi²) is in a favorable depth range, based on available cross-sectional data, the new PEMEX map indicates that the true prospective area in the Veracruz Basin could be much smaller, perhaps only 960 mi². This yields a reduced estimate of 3 Tcf and 0.3 billion barrels of risked technically recoverable shale gas and shale oil resources for the Maltrata Formation in the Veracruz Basin, out of 21 Tcf and 7 billion barrels of risked shale gas and shale oil in-place.

5.4 Recent Activity

PEMEX plans to drill up to 10 shale exploration wells in the Veracruz Basin in the next three years.
